

# The James Webb Space Telescope: Thermal Testing Considerations

**William M. Bell**

**Mechanical Engineer  
Topsfield Engineering  
Service, Inc.**

**August 7, 2006**

# The conventional Thermal Vacuum Chamber thermal control system (TCS) operates down to 80 K

Provide uniform 80 K temperature background

Provide an thermally absorptive background surface – black paint

Shroud assembly is only “light-tight”

Chamber operation at  $1 \times 10^{-5}$  torr

# JWST ground testing requires an additional “20 K” shroud to simulate space flight conditions at L2

Cool test article at 35 K to qualify the design

Provide uniform testing temperature background

Refrigeration capacity at 20 K for heat load

# Thermal Conditioning System design parameters

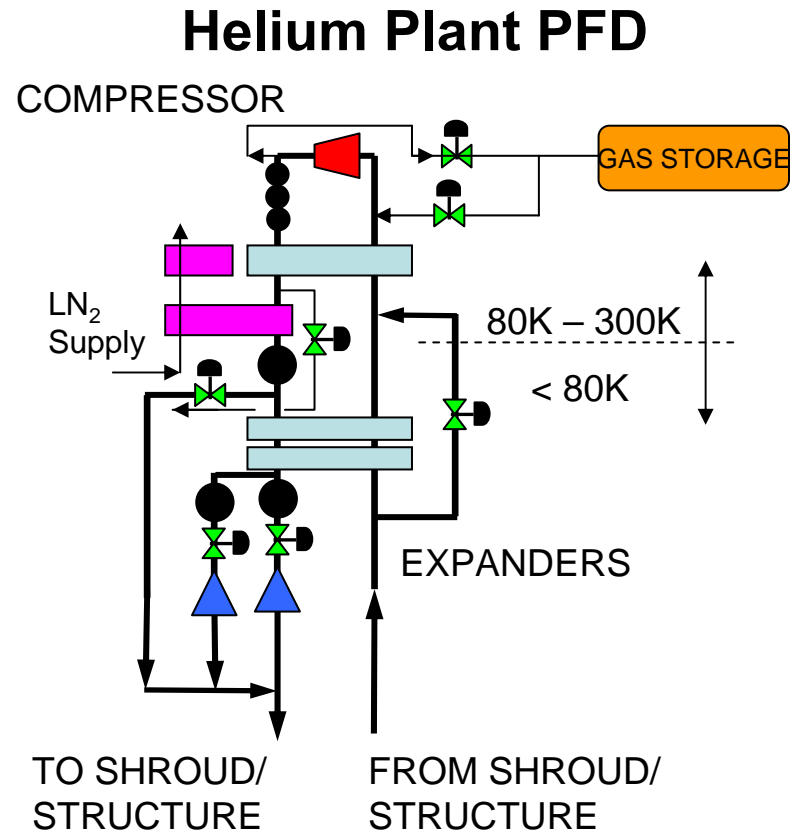

Provide for controlled cool-down, soak, and warm-up of JWST Test Assembly

Hold to a set point temperature, within  $\pm 1$  K, during steady state conditions at any temperature from 340 K to 20 K.

Be capable of taking the Test Assembly from 300 K, and under vacuum, to 35 K and steady state within 10 days.

# Additional test equipment modeling detail

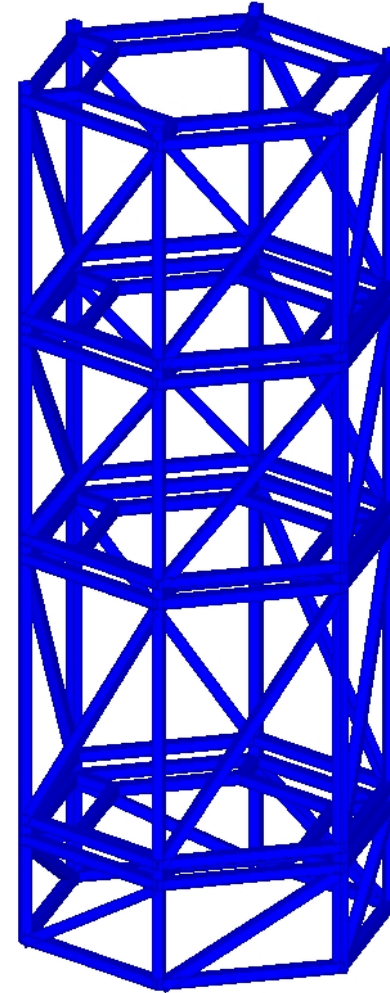

Test Article in various configurations - JWST, Pathfinder, etc. This is assumed to weigh 8000 lbs, have a surface area of 1000 m<sup>2</sup> (emissivity = 0.7), and a heat load of 1000 watts. These figures include all test equipment - flats, interferometers, etc

Test Support structure, including heated isolators. The inner structure is assumed to weigh 190,000 lbs and the outer structure is assumed to weigh 60,000 lbs. Both structures are constructed from stainless steel

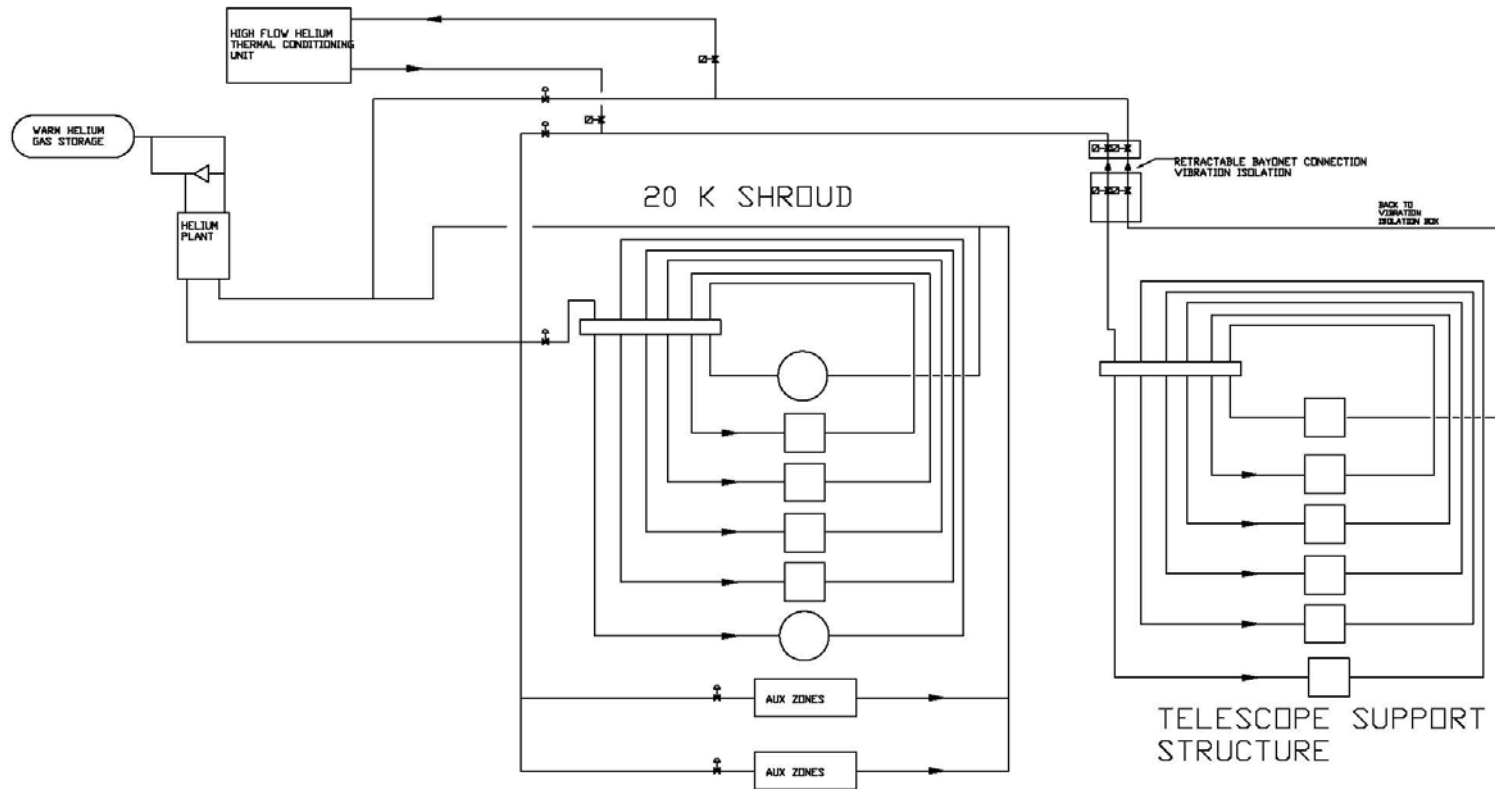

# The Test Support Structure is conditioned with He gas mass flow

The Helium gas mass flow is pumped through tracing tubes bonded to the structure or directly through the structural tubing

# The Helium Flow Diagram

This is one possible concept for the Helium Conditioning System

# A “light-tight” shroud is typically constructed of “batwings” and “chevrons”

Aluminum “batwing” extrusion

Aluminum “chevron” extrusion assembly – good for vacuum pumping

Interlocked Extrusions

Header

Typical shroud assembly

# The conventional T/V TCS provides for thermal conditioning by radiation and conduction

$$Q = ak/l(\Delta t)$$

Conduction

$$Q_r = \sigma FA(T_h^4 - T_c^4) - \text{Radiation}$$

For a given surfaces and constant  $\epsilon$  &  $\alpha$ , 30 K to 20 K radiation heat flow is 1/38<sup>th</sup> of 90 K to 80 K radiation heat flow

It may not be possible to reach 35 K relying on radiative heat transfer at these temperatures

# What other heat transfer options are there?

## Molecular and Continuum Conduction

Sutherlin, S., The X-Ray Calibration Facility (XRCF) Thermal Characterization Test Cycle 3 Data Correlation, 12/20/2002

## Natural Convection at reduced pressure

Bell, W., Kudirka, F., Young, P-W, James Webb Space Telescope Thermal Conditioning Study, 6/29/2004

These options are available within Thermal Desktop

# The Sutherlin study shows test results at 30 K

Gaseous heat transfer and flow regimes are defined in terms of the Knudsen number, Kn

Continuum	$Kn < 0.01$
Mixed	$0.01 < Kn < 0.30$
Free-molecular	$Kn > 0.30$

Test Article temperature went from 60 K to 31 K by injecting He gas into the T/V Chamber, increasing Chamber pressure from 3e-06 torr to 5e-04 torr

# Bell, et al, built on the Sutherlin study and considered natural convection at reduced pressure

$$\text{Nu}_p = C(\text{Gr}_p \text{Pr})^n - \text{Natural Convection (enhanced conduction)}$$

Basis of correlations and values of  $C$  are typically derived from data with air at atmospheric pressure  
Natural Convection relies on density differences.

The density difference for a 10 C difference in air temperature is  $290/300$ , or 0.967

For Helium gas inside the 20 K shroud this ratio is  $25/35$ , or 0.714

# Natural convection works on all surfaces

**Some components of the Test Article cannot be traced or tied to a cold surface with a conductive strap**

# Major difference in thermal control system design

**The cold Helium gas within the 20 K & 80 K shrouds must be prevented from flowing over the Chamber surfaces**

# Simplified Thermal Desktop Model

**Nodes:** 33  
**Linear Conductors:** 46  
**Radiation Conductors:** 58  
**Lumps:** 3  
**Paths:** 2  
**Ties:** 7

**The Test Article is modelled as a cylinder and a node represents the Test Support thermal mass and area**

# Alternative Cool-Down options modeled

## Radiation only - 1

## Radiation and Natural Convection – 2 and 4

**Thermal Desktop provides means to include molecular conduction and natural convection**

# Modeling natural convection at reduced pressure

Comment: **Natural Convection of He gas at dpress within He shroud to TA**

Submodel: **MAIN**

**Thermal Desktop simplifies this once laborious task**

# Thermal Model Surface Finish/Emissivity

Item	Description	Surface	Emissivity i/o
1.	SPF Chamber Inner	Bare Aluminum	0.10
2.	80 K Shroud Outer	Bare Aluminum	0.10
3.	80 K Shroud Inner	Z307	0.87
4.	20 K Shroud Outer	Bare Aluminum	0.10
5.	20 K Shroud Inner	Z307	0.87
6.	Test Article/Structure	SS304L/Z307	0.15/.7
7.	SPF Chamber Outer	Bare Aluminum	0.10

Temperature varying emissivity was not used in this analysis, however, Thermal Desktop can now do this

# Modeling results for $h_{nc}$ are reasonable and should be confirmed by testing

A typical natural convection  $h$  is  $3.2 \text{ w/m}^2 \text{ K}$  for air and a  $\Delta T$  of  $8 \text{ K}$  –  $T_{\text{air}} = 290 \text{ K}$ ,  $P = 760 \text{ torr}$ , &  $l = 12 \text{ in}$

From Model 4b results, the  $h$  is  $0.22 \text{ w/m}^2 \text{ K}$  –  $T_{\text{he}} = 30 \text{ K}$ ,  $P = 1 \text{ torr}$ , &  $l = 768 \text{ in}$

For  $l = 12 \text{ in}$ , the  $h$  goes to  $0.65 \text{ w/m}^2 \text{ K}$

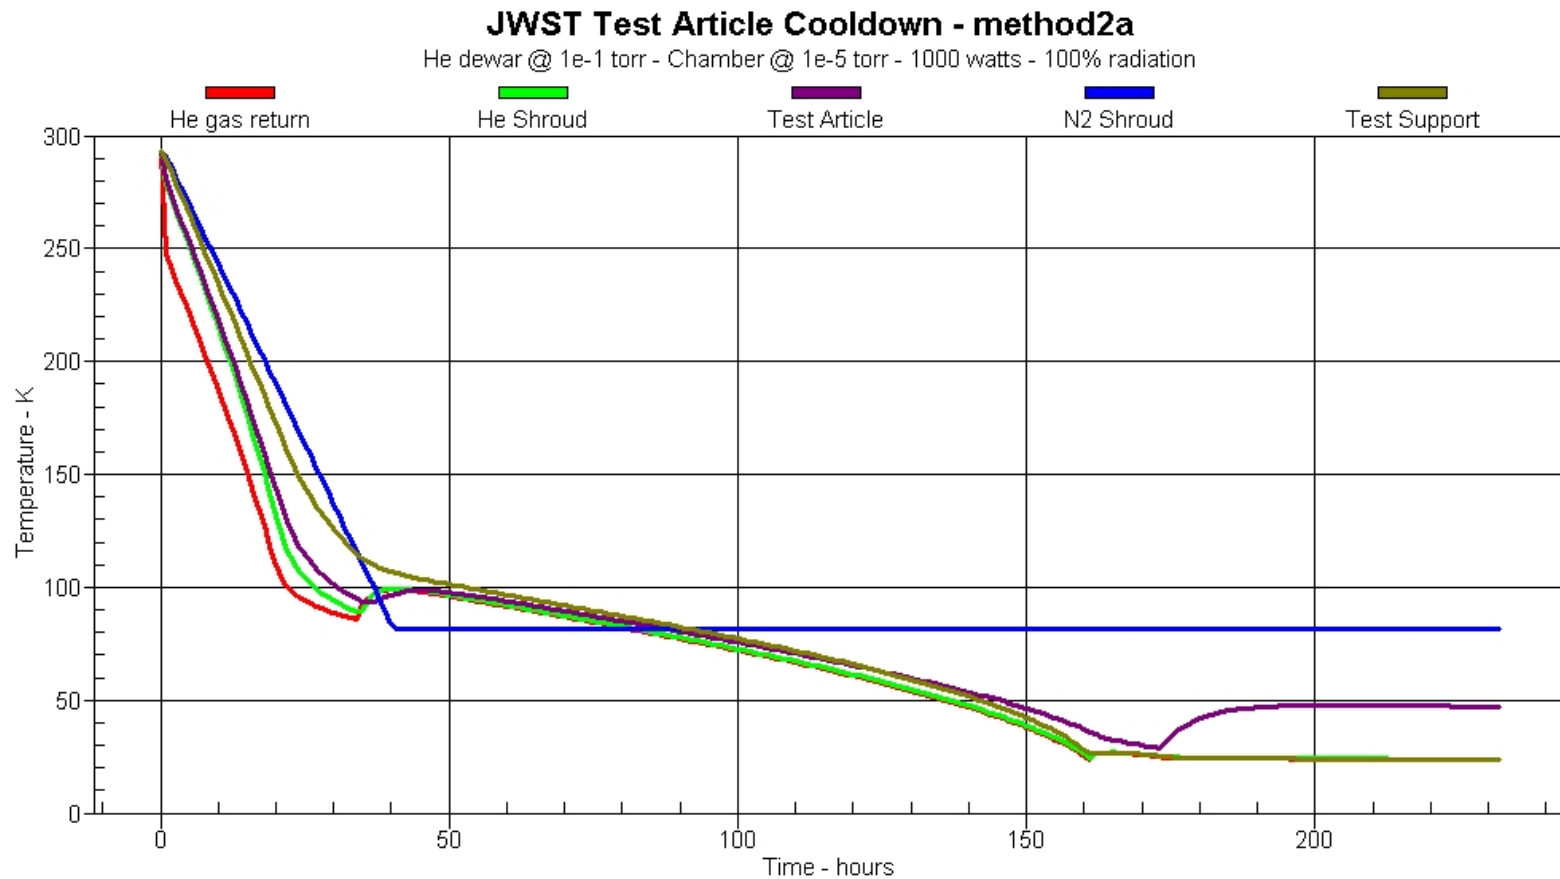

# Method 1a Cool-down results

**After cooling to 43 K in 170 hours, the test article heats up to 69 K after the 1000 watt radiative load is applied**

# Method 2a Cool-down results

**After cooling to 28 K in 173 hours, the test article heats up to 47 K after the 1000 watt radiative load is applied**

# Method 2b Cool-down results

**After cooling to 25 K in 173 hours, the test article heats up to 35 K after the 1000 watt radiative load is applied**

# Method 4a Cool-down results

**After cooling to 33 K in 170 hours, the test article heats up to 60 K after the 1000 watt radiative load is applied**

# Method 4b Cool-down results

Note: He refrigerator size has doubled

After cooling to 33 K in 90 hours, the test article heats up to 37 K after the 1000 watt radiative load is applied

# The Thermal Control System design must include:

**Clean Room Conditions**

**Vacuum Pumping System**

**Support Thermal &  
Vibration Isolation**

**Material Properties**

**Optical Test Requirements**

**Electrical – corona effect**

# In summary, natural convection is a viable mode of heat transfer for thermal conditioning

Application of natural convection must be consistent with testing goals

There are important differences in the design of thermal control systems

Works on all surfaces and reduces thermal gradients

Testing is needed to verify that correlations work under reduced pressure and temperature conditions
