Thermal & Fluids Analysis Workshop
TFAWS 2023
August 21-25, 2023
NASA Goddard Space Flight Center
College Park, MD

Computing radiative heat transfer with view factors or ray tracings is the most time-consuming part

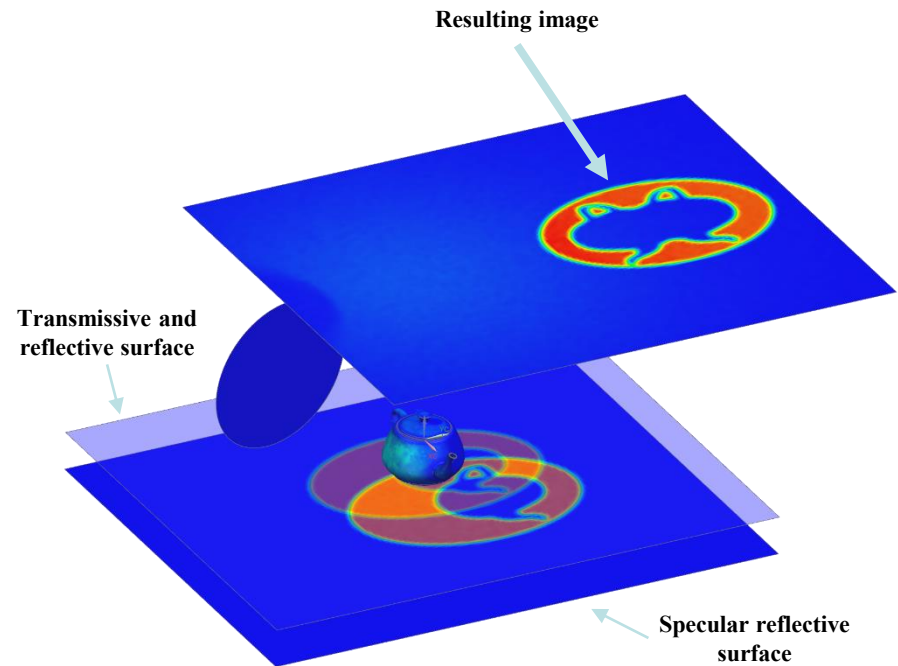

It can take **days** to get the results of a single simulation for high fidelity **detailed** models (~50k-100k elements)

- Capability added to Simcenter 3D Thermal Multiphysics and Space systems thermal since 2021
- view factor calculation is a perfect type of calculation to be performed on Graphics Processing Units or GPUs since these calculations can be performed in parallel on the hundreds of cores that a typical GPU processes.
- View factor computations and ray tracing is performed on NVIDIA GPUs, based on a modified Monte Carlo ray tracing method implemented using CUDA v11.8.
- Support for both diffuse and advanced thermo-optical surface properties including specular reflectivity, transmissivity, and refraction.

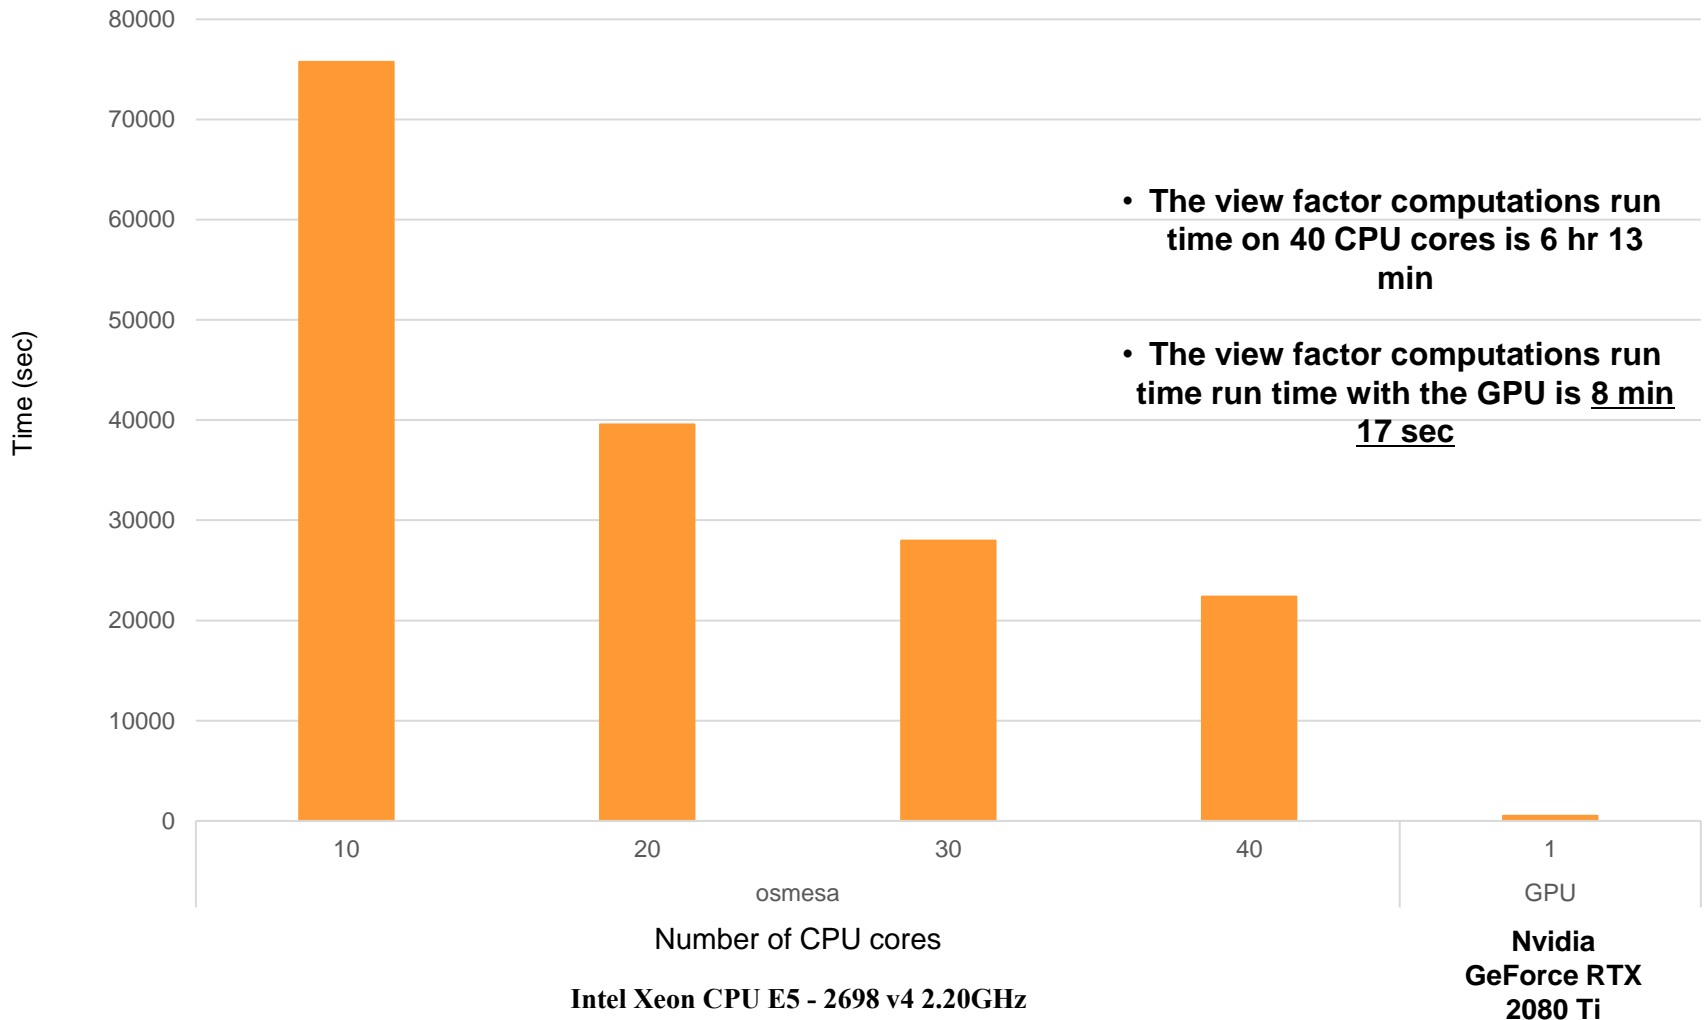

- Actively supported and improved
- Ability to program at lower level
 - **More easily tune solve process**
 - **Optimize based on application needs**
- Rich supporting toolset
- Partnership with NVIDIA and ongoing collaboration

- The Monte Carlo computation method is a ray-casting or ray-tracing method used in many applications including the calculation of view factors.
- Rays are launched in random directions from the j th element
- The fraction of rays that hits the k th element is used to compute the view factor from j to k
- Number of rays cast influences results accuracy and precision
- The GPU implementation is a modified implementation of the Monte Carlo method.

View Factor Computations Run Time

Model	Number of elements
Teapot	168,929

Customer models	Number of elements
Model 1	700,910
Model 2	813,000
Model 3	445,487
Model 4	511,687

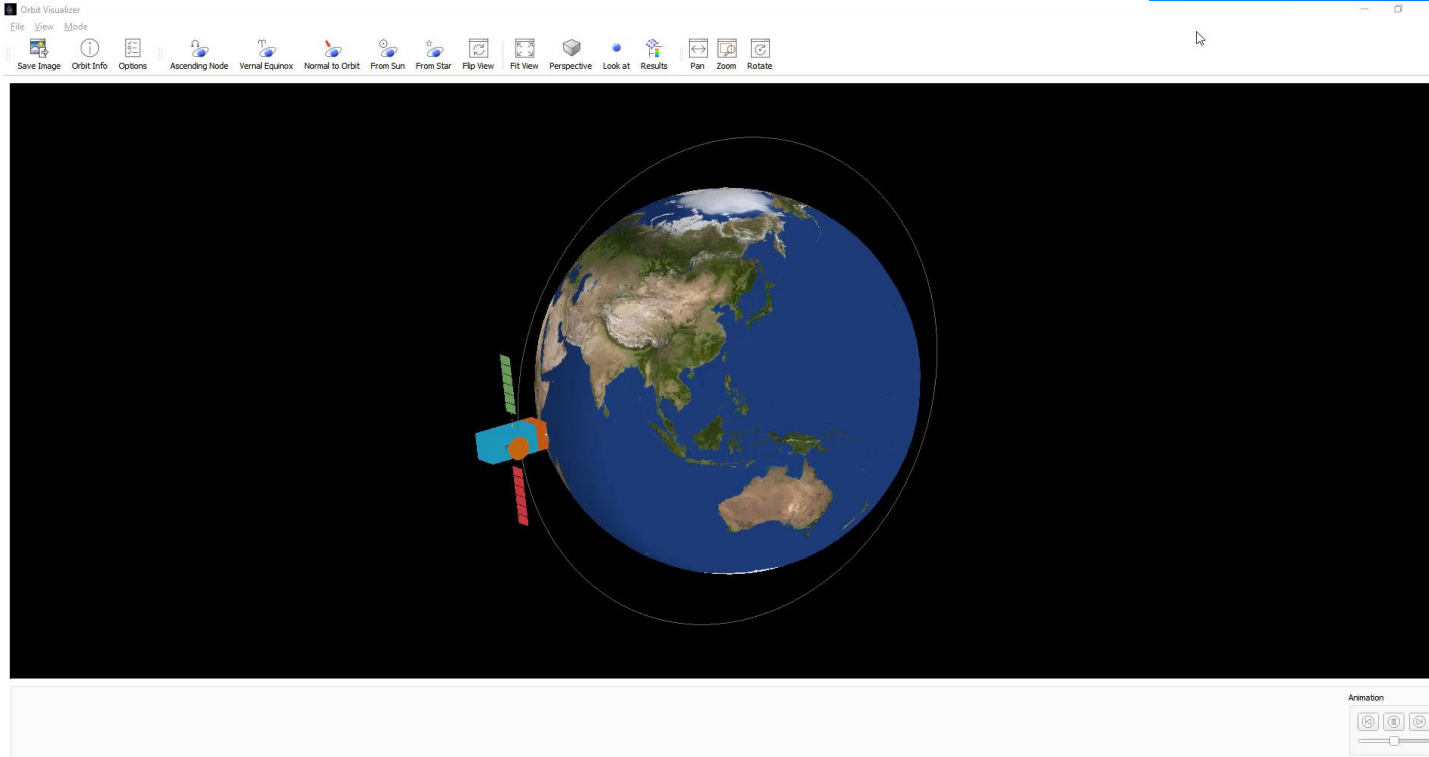

Ray tracing time (s)			
	CPU Monte Carlo	GPU ray tracing	Improvement
Teapot	3,681	252	15x

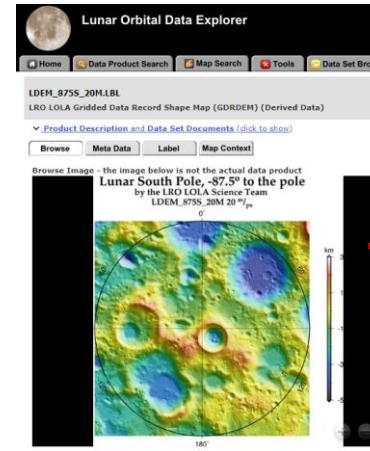

View Factor Computation Time (S)			
	CPU view factors	GPU view factors	Improvement
Model 1	8 cores: 68,050	1,451	46x
Model 2	6 cores: 44,436	1,307	34x
Model 3	6 cores: 118,406*	297	399x
Model 4	6 cores: 127,233*	311	409x

Extending to Solar and Orbital Fluxes

- In order to fully test our new implementation for the GPU we used a detailed Moon Surface model.
- This model was created, based on NASA Lunar Handbook methodology:
 - The topography for the zone of interest is retrieved from the NASA database
 - A custom script converts the binary files to an NX-readable format
 - The thermal model is prepared using properties correlated from surface temperature measurements (from NASA's LRO mission)

```

# Read binary data file
data_file = io.open(input_file, 'r')
raw_data = data_file.read()
data = struct.unpack('f' * LDEM_LINE_SAMPLES, raw_data)

# Initialize stuff for loop
res = []
i = 1
j = 1

# Loop through the dataset
for val in data:
    # Convert i-j coordinates to DEM coordinates with 0,0 at the center
    Xmap = (i - N/2) * 0.5 * MAP_SCALE
    Ymap = (j - N/2) * 0.5 * MAP_SCALE

    # Radius from center of disc in local i,j in meters
    Rmap = (Xmap**2 + Ymap**2)**0.5

    # Convert DEM coordinates to planetocentric spherical (LAT [Deg], LON [Deg],
    LON = math.atan2(Ymap, Xmap) * 180/math.pi # Note: removed math.pi, longitude
    r0 = (val * SCALING_FACTOR + OFFSET) * 1000

    # Verify if file is for N or S hemisphere (different formula for latitude)
    if input_file[-1] == 'S':
        LAT = -math.asin(r0 / Rmap * math.atan(0.5 * Rmap / 1737400))
    elif input_file[-1] == 'N':
        LAT = 90 - 180 / math.pi * math.atan(0.5 * Rmap / 1737400)
    else:
        print('Latitude cannot be computed. Did you rename the file?')
        exit

    # Convert spherical to cartesian coordinates (x,y,z in [m])
    x = r0 * math.cos(LAT) * math.pi / 180 + math.cos(LON * math.pi / 180)
    y = r0 * math.sin(LAT) * math.pi / 180 + math.sin(LON * math.pi / 180)
    z = r0 * math.sin(LAT) * math.pi / 180

    # Output only points within the bounding box
    output_str = [(x-vec[0]), (y-vec[1]), (z-vec[2])]
    if LON == bin[0] and LON == bin[1]:
        if abs(LAT) == abs(bin[2]) and abs(LAT) == abs(bin[1]):
            res.append(output_str)
    
```

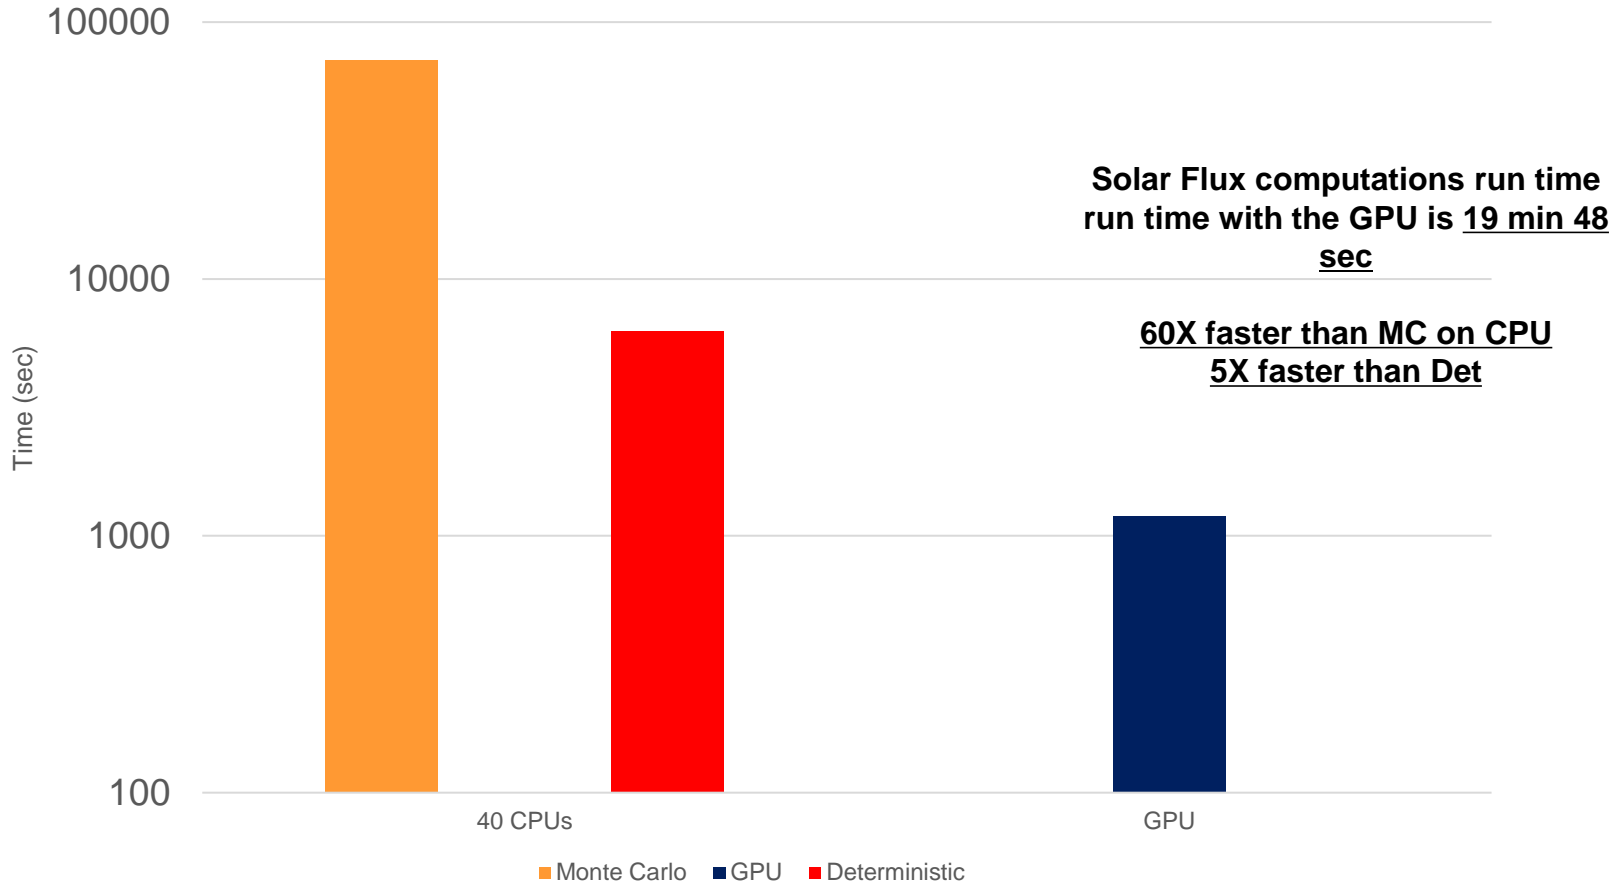

2km square at 5m, a 16km square at 20m, and the remainder of 88.5 deg S to Pole at 240m resolution

360 positions (1 lunar day cycle, every ~2 hours)

CPU vs GPU Montecarlo Solar Heating

Conclusion

- GPU Enclosure radiation and solar heating calculation will be an early access feature in Simcenter 3D 2312

- Next for Simcenter 2406 (June 2024):
 - Add Earth IR and Albedo calculations to the GPU orbital heating algorithm
 - Parabolic Elements
 - Optimize GPU algorithm further for Articulation/spinning models

Thank You!
